At the end of this module, students will be able to...

- C1. Constant coefficient first order.** ...find the general solution to a first order constant coefficient ODE.
- C2. Modeling motion in viscous fluids.** ...model the motion of a falling object with linear drag
- C3. Homogeneous constant coefficient second order.** ...find the general solution to a homogeneous second order constant coefficient ODE.
- C4. IVPs.** ...solve initial value problems for constant coefficient ODEs
- C5. Non-homogenous constant coefficient second order.** ...find the general solution to a non-homogeneous second order constant coefficient ODE
- C6. Modeling oscillators.** ...model (free or forced, damped or undamped) mechanical oscillators with a second order ODE

## Readiness Assurance Outcomes

Before beginning this module, each student should be able to...

- Describe Newton's laws in terms of differential equations.
- Find all roots of a quadratic polynomial.
- Use Euler's theorem to relate  $\sin(t)$ ,  $\cos(t)$ , and  $e^t$ .
- Use Euler's theorem to simplify complex exponentials.
- Use substitution to compute indefinite integrals.
- Use integration by parts to compute indefinite integrals.
- Solve systems of two linear equations in two variables.

**Activity C.1.2** ( $\sim 5$  min)

List all of the forces acting on a tiny droplet of water falling from the sky.

**Activity C.1.3** ( $\sim 5$  min)

Tiny droplets of water obey **Stoke's law**, which says that air resistance is proportional to (the magnitude of) velocity.

- Let  $v$  be the velocity of a droplet of water (positive for upward, negative for downward).
- Let  $g > 0$  be the magnitude of acceleration due to gravity and  $b > 0$  be another positive constant.

Apply Newton's second law (force = mass  $\times$  acceleration) to determine which of the following **ordinary differential equations (ODEs)** models the velocity of a falling droplet of water.

(a)  $v' = g - v$

(b)  $v' = g + v$

(c)  $mv' = -mg - bv$

(d)  $mv' = -mg + bv$

## Observation C.1.4

The modeling equation

$$mv' = -mg - bv$$

may be obtained by splitting the total force into gravity and air resistance:

$$F = F_g + F_r$$

Then  $F = ma = mv'$  and  $F_g = m(-g) = -mg$  are the result of Newton's second law, and  $F_r = -bv$  holds because it should be (a) in the opposite direction of velocity and (b) a constant multiple of velocity.

Note that this equation may be rearranged as follows to group  $v$  and its derivative  $v'$  together on the left-hand side:

$$v' + \left(\frac{b}{m}\right)v = -g$$

## Definition C.1.5

A **first order constant coefficient** differential equation can be written in the form

$$y' + by = f(x),$$

or equivalently,

$$\frac{dy}{dx} + by = f(x).$$

We will use both notations interchangeably.

Here, **first order** refers to the fact that the highest derivative we see is the first derivative of  $y$ .

## Observation C.1.6

Consider the differential equation  $y' = y$ .

A useful way to visualize a first order differential equation is by a **slope field**

Each arrow represents the slope of a solution **trajectory** through that point.

## Definition C.1.9

A differential equation will have many solutions. Each individual solution is said to be a **particular solution**, while the **general solution** encompasses **all** of these by using parameters such as  $C$ ,  $k$ ,  $c_0$ ,  $c_1$  and so on. For example:

- The general solution to the differential equation  $y' = 2x - 3$  is  $y = x^2 - 3x + C$  (as done in Calculus courses).
- The general solution for  $y' = y$  is  $y = ke^x$  (as done in the previous activity).

## Observation C.2.1

Recall that we can model the velocity of a water droplet in a cloud by

$$mv' = -mg - bv$$

where negative numbers represent downward motion,  $m > 0$  is the mass of the droplet,  $g > 0$  is the magnitude of acceleration due to gravity, and  $b > 0$  is the proportion of wind resistance to speed.

**Activity C.2.2** (*~20 min*)

A water droplet with a radius of  $10\ \mu\text{m}$  has a mass of about  $4 \times 10^{-15}\ \text{kg}$ . It is determined in a laboratory that for a droplet this size, the constant  $b$  has a value of  $3 \times 10^{-3}\ \text{kg/s}$ , and it is known that  $g$  is approximately  $9.8\ \text{m/s}^2$ .

Complete the following tasks to study the motion of this droplet.

**Activity C.3.4** (*~15 min*)

Consider the mass-spring equation  $my'' = -ky$  where  $m = k = 1$ :

$$y'' = -y.$$

*Part 1:* Find a solution.

*Part 2:* Find the general solution.

*Part 3:* Describe the long term behavior of the mass-spring system.

**Activity C.3.5** ( $\sim 5$  min)

The general solution  $y = c_1 \cos(t) + c_2 \sin(t)$  models infinitely oscillating behavior, but in applications this does not occur.

Thus, a damper (a.k.a. dashpot) is often considered, which provides a force proportional to velocity, given by the coefficient  $b > 0$ . For example, friction may act as a damper to a mass-spring system.

Write a differential equation modeling the displacement of a mass in a **damped** mass-spring system.

### Observation C.3.6

The damped mass-spring system can be modelled by

$$my'' = -by' - ky.$$

Here  $m$  is the mass,  $k$  is the spring constant, and  $b$  is the damping constant. We can rearrange this as

$$y'' + By' + Ky = 0$$

where  $B = \frac{b}{m}$  and  $K = \frac{k}{m}$ .

This is a **homogeneous second order constant coefficient** differential equation. Here, **homogeneous** refers to the 0 on the right hand side of the equation.

## Observation C.3.8

It is sometimes useful to think in terms of **differential operators**.

- We will use  $D$  to represent a derivative. So for any function  $y$ ,

$$D(y) = \frac{\partial y}{\partial x} = y'.$$

- $D^2$  will denote the second derivative operator (i.e. differentiate twice, or apply  $D$  twice).
- We will use  $I$  for the identity operator, so  $I(y) = y$ . (It can be thought of as  $I = D^0$ , take the derivative zero times.)

In this language, the differential equation  $y' + 3y = 0$  can be rewritten as  $D(y) + 3I(y) = 0$ , or more simply  $(D + 3I)(y) = 0$ .

Thus, the question of solving the homogeneous differential equation is the question of finding the **kernel** of the differential operator  $D + 3I$ : all the functions  $y$  that the transformation  $D + 3I$  turns into the zero function.

Consider the homogeneous second order constant coefficient ODE

$$ay'' + by' + cy = 0.$$

When does the general solution have the form  $c_0e^{rt} + c_1te^{rt}$  ?

- (a) When the polynomial  $ax^2 + bx + c$  has two distinct real roots.
- (b) When the polynomial  $ax^2 + bx + c$  has a repeated real root.
- (c) When the polynomial  $ax^2 + bx + c$  has two distinct non-real roots.
- (d) When the polynomial  $ax^2 + bx + c$  has a repeated non-real root.

### Observation C.3.24

Consider the homogeneous second order constant coefficient ODE

$$ay'' + by' + cy = 0$$

given by the differential operator  $aD^2 + bD + cI$ . Let  $r$  be a (possibly non-real) solution to  $ax^2 + bx + c = 0$ :

- $e^{rt}$  is a particular solution of the ODE.
- If  $r$  is a double root,  $te^{rt}$  is also a particular solution.
- if  $r = \alpha + \beta i$  is not real, Euler's formula allows us to express the real-valued solutions in terms of  $\sin(\beta t)$  and  $\cos(\beta t)$ .

Due to the usefulness of its solutions,  $ax^2 + bx + c = 0$  is called the **auxiliary equation** for this ODE.

*Part 1:* Use the product rule (twice) to compute  $y_p'$ .

*Part 2:* To simplify calculations, we will **assume**  $v_1'y_1 + v_2'y_2 = 0$ . Assuming this, compute  $y_p''$ .

*Part 3:* Compute  $\mathcal{L}(y_p)$ ; simplify the ODE  $\mathcal{L}(y_p) = f(x)$ .

**Observation C.9.4**

If we can find  $v_1$  and  $v_2$  that satisfy

$$y_1 v'_1 + y_2 v'_2 = 0$$

$$y'_1 v'_1 + y'_2 v'_2 = \frac{f}{a}$$

then we have a solution. So we just need to solve this system of equations for  $v'_1$  and  $v'_2$ .
