At the end of this module, students will be able to...

- C1. Constant coefficient first order.** ...find the general solution to a first order constant coefficient ODE.
- C2. Modeling motion in viscous fluids.** ...model the motion of a falling object with linear drag
- C3. Homogeneous constant coefficient second order.** ...find the general solution to a homogeneous second order constant coefficient ODE.
- C4. IVPs.** ...solve initial value problems for constant coefficient ODEs
- C5. Non-homogenous constant coefficient second order.** ...find the general solution to a non-homogeneous second order constant coefficient ODE
- C6. Modeling oscillators.** ...model (free or forced, damped or undamped) mechanical oscillators with a second order ODE

Readiness Assurance Outcomes

Before beginning this module, each student should be able to...

- Describe Newton's laws in terms of differential equations.
- Find all roots of a quadratic polynomial.
- Use Euler's theorem to relate $\sin(t)$, $\cos(t)$, and e^t .
- Use Euler's theorem to simplify complex exponentials.
- Use substitution to compute indefinite integrals.
- Use integration by parts to compute indefinite integrals.
- Solve systems of two linear equations in two variables.

Activity C.1.3 ($\sim 5 \text{ min}$)

Tiny droplets of water obey **Stoke's law**, which says that air resistance is proportional to (the magnitude of) velocity.

- Let v be the velocity of a droplet of water (positive for upward, negative for downward).
- Let $g > 0$ be the magnitude of acceleration due to gravity and $b > 0$ be another positive constant.

Apply Newton's second law (force = mass \times acceleration) to determine which of the following **ordinary differential equations (ODEs)** models the velocity of a falling droplet of water.

- (a) $v' = g - v$
(b) $v' = g + v$
(c) $mv' = -mg - bv$
(d) $mv' = -mg + bv$

Section C.4

Section C.5

Section C.6

Section C.7

Section C.8

Section C.9

Observation C.1.4

The modeling equation

$$mv' = -mg - bv$$

may be obtained by splitting the total force into gravity and air resistance:

$$F = F_g + F_r$$

Then $F = ma = mv'$ and $F_g = m(-g) = -mg$ are the result of Newton's second law, and $F_r = -bv$ holds because it should be (a) in the opposite direction of velocity and (b) a constant multiple of velocity.

Note that this equation may be rearranged as follows to group v and its derivative v' together on the left-hand side:

$$v' + \left(\frac{b}{m}\right)v = -g$$

Definition C.1.5

A **first order constant coefficient** differential equation can be written in the form

$$y' + by = f(x),$$

or equivalently,

$$\frac{dy}{dx} + by = f(x).$$

We will use both notations interchangeably.

Here, **first order** refers to the fact that the highest derivative we see is the first derivative of y .

Definition C.1.9

A differential equation will have many solutions. Each individual solution is said to be a **particular solution**, while the **general solution** encompasses **all** of these by using parameters such as C, k, c_0, c_1 and so on. For example:

- The general solution to the differential equation $y' = 2x - 3$ is $y = x^2 - 3x + C$ (as done in Calculus courses).
- The general solution for $y' = y$ is $y = ke^x$ (as done in the previous activity).

Observation C.2.3

The technique outlined in the previous activity is called **variation of parameters**.

If y_0 is a particular solution of the **homogeneous** equation, assume that a particular solution of the **non-homogeneous** equation has the form $y_p = vy_0$, and then determine what v must be.

Example:

$$\begin{array}{ll} y' + 3y = 0 & \text{homogeneous} \\ y' + 3y = x & \text{non-homogeneous} \end{array}$$

Note that each term of the homogeneous equation includes y or its derivatives.

Section C.9

Observation C.5.1

It is sometimes useful to think in terms of **differential operators**.

- We will use D to represent a derivative; another common notation is $\frac{\partial}{\partial x}$. So for any function y ,

$$D(y) = \frac{\partial y}{\partial x} = y'.$$

- D^2 will denote the second derivative operator (i.e. differentiate twice, or apply D twice).
- We will use I for the identity operator; it does nothing to a function. That is, $I(y) = y$. It can be thought of as $I = D^0$ (i.e. differentiate zero times).

In this language, the differential equation $y' + 3y = 0$ can be rewritten as $D(y) + 3I(y) = 0$, or $(D + 3I)(y) = 0$.

Thus, the question of solving the homogeneous differential equation is the question of finding the **kernel** of the differential operator $D + 3I$.

Observation C.7.2

To solve this, we need to find the kernel of $(D - 2I)(D - 2I)$.

- The kernel of $D - 2I$ is $\{ce^{2t} \mid c \in \mathbb{R}\}$.
- However, if $(D - 2I)(y) = Ae^{2t}$, then applying $D - 2I$ twice will yield zero!
- So we must solve the ODE

$$y' - 2y = e^{2t}.$$

Activity C.9.6 (~ 10 min)

Consider the nonhomogeneous ODE $y'' + 9y = \sin(3t)$.

Part 1: Find v_1 and v_2 by solving

$$\cos(3t)v'_1 + \sin(3t)v'_2 = 0$$

$$-3\sin(3t)v'_1 + 3\cos(3t)v'_2 = \sin(3t)$$

Part 2: Write the general solution of the original nonhomogeneous ODE.
